Abstract This paper aims to reveal the relationship and structure of library and information science (LIS) journals in China. 24 core LIS journals in China are selected and the relevant data of journal co-citation are retrieved from Chinese Journal Full-Text Database constructed by China National Knowledge Infrastructure during the period of 1999–2009. By calculating mean co-citation frequencies and correlation coefficients, we find that there is a strong relationship among LIS journals in China. Utilizing the methods of cluster analysis, multidimensional scaling analysis and factor analysis, we analyze the data of journal co-citation. LIS journals in China are divided into four clusters. The relatedness among journals is shown manifestly through their locations in the two-dimensional map. A three-factor solution is obtained with the factor loading of each journal. Finally, we interpret and discuss the results to get some conclusions and also expect to describe the network characters of journal co-citation in future research.

Keywords China · LIS journals · Journal co-citation · Multivariate statistical analysis

Introduction

During recent years, Library and Information Science (LIS) in China has been changed dramatically along with the reform and opening policy of China and the rapid growth of Chinese economy (Wu and Yuan 1994). LIS in China has achieved remarkable advances with several research branches emerging at present, namely: basic theories and methods of information science, bibliometrics, digital library, information service, information resource management, document index, information retrieval theory and competitive intelligence, etc. (Ma et al. 2009). As the important carrier of research achievement, LIS core journals in China are selected respectively by “Guide to the Chinese Core Journals” of Peking University Library and Chinese Social Science Citation Index (CSSCI: <http://cssci.nju.edu.cn/lyk2010/tq.htm>) of Nanjing University every year. “Chinese Journal

Highlycited Indicators” published by Chinese Scientific and Technical Information Institute and Wanfang Data Co., Ltd. demonstrates the basic status of LIS journals in China through the number of published articles, the cited frequencies, impact factor, etc. These works only reveal the properties of individual journal; meanwhile, until now few articles focus on the relationship and structure of LIS journals in China. This paper aims to use journal co-citation analysis (JCA) to identify the relationship and structure of LIS in China.

Co-citation means that two items (documents, authors and journals, etc.) are cited when they are listed in a citing item’s reference list. The basic assumption of co-citation analysis is that the more frequently two items are co-cited, the more closely they are linked together. Co-citation analysis was first presented by Small (1973) in the early 1970s to examine the relationship and structure of an academic field, and proved to be an effective method to analyze the communication patterns through the published literatures (Small and Griffith 1974). Since then, co-citation analysis has been widely used to reveal the relationship and structure of an academic field in terms of authors, articles, journals or keywords (e.g., McCain 1990; Ma et al. 2009; Zhao et al. 2009; Liu 2005b; Zitt et al. 2003). McCain (1991) first attempted to utilize journal co-citation analysis and manifested that journal co-citation analysis could produce clear, coherent and reasonable results to help the researchers to study the structure of an academic field in which scholarly journals are a major means of communication. Among related studies, it has been shown that journal co-citation analysis can be used as an operational indicator for the discipline organization of the sciences, such as: information retrieval (Ding et al. 2000), semiconductor (Tsay et al. 2003), urban studies (Liu 2005b), etc. Furthermore, social network analysis (SNA) is applied in journal co-citation to show the network structure of journals (Yue and Liu 2008).

At present, scholars usually cluster analysis, multidimensional scaling analysis and factor analysis to conduct co-citation analysis. Compared to the scholars’ traditional qualitative analysis (including individual induction, interviews and other subjective methods), co-citation analysis is more scientific, objective and effective (Liu 2005a).

By applying JCA, We manage to map the intellectual structure of LIS in China during the time period of 1999–2009, mainly including the status of any two journals co-cited, the relationship among journals and the subject areas that journals cover, and the reasonable interpretation according to actual situation of journals. The results of the study will help us to understand the scholarly communication in the field of LIS in China and benefit LIS scholars and researchers in terms of grasping the intellectual structure as reflected in its published journals. Additionally, the results may also guide information providers to collect and manage the related academic journals in LIS.

Method and data collection

The study followed the steps outlined by McCain (1991). Firstly, respective journals are selected and paired with other journals in the journal set. The co-citation frequencies of the paired journals are retrieved from the citation database and put into the square symmetric journal co-citation matrix with the data in the diagonal cells treated as missing data. Afterwards, the co-citation frequencies matrix is converted into a matrix of correlation coefficients, served as the measure of similarity. Then, the correlation matrix is analyzed using the statistical procedures of cluster analysis, multidimensional scaling analysis and factor analysis. Finally, the results are interpreted and confirmed.

Journal selection

We select 24 journals from “Chinese Journal Highlycited Indictors (CJHI)” (impact factor greater than 0.6) (Zeng 2009). The list of those journals and their general citation information acquired from CJHI are presented in Table 1. These 24 journals are capable of representing the major scholarly communication and collaboration patterns of LIS research in China.

Data collection of journal co-citation

Chinese Journal Full-Text Database (CJFTD) is the biggest Chinese journal full-text database and is updated continuously and dynamically every day. CJFTD embraces all Chinese LIS journals with the retrieval function for journal co-citation. Therefore, we

ISTA	977	1,554	1,804	950	485	930	2,374	854	2,155	

chose CJFTD as the data source to conduct this study. Taking use of the retrieval function for JCA, the selected journals were paired and put in the retrieval items of “reference” and time span was defined between 1999 and 2009; and then the number of eligible papers was retrieved. Finally we obtained $(24 \times 23)/2 = 276$ different sets of data, and put into the matrix. The matrix is a symmetric matrix with the data in the diagonal cells treated as missing data and the values of non-diagonal cell were the co-citation frequencies (shown in Table 2).

Method of data analysis

SPSS13.0 and Ucinet6.0 are employed in this study. In order to illustrate the relationship of these journals, we utilize Pearson method (White 2003) to convert the original matrix into a correlation matrix (shown in Table 3). The hierarchical agglomerative cluster analysis with Ward’s method is conducted on the correlation data to determine the clusters of journals (Small et al. 1985). And a two-dimensional map is created by MDS (ALSCAL) to intuitively reflect the correlation degree through the location of journals in the map (Norusis 1997). Furthermore, factor analysis is used to complement the cluster analysis and multidimensional scaling analysis in this study and show a journal’s contribution to LIS (White and McCain 1998). In factor analysis, the journal can load on more than one factor unlike cluster analysis in which a journal is only assigned to one cluster. And the factors are extracted by principal component analysis with varimax rotation (Hung 2004).

Results and discussion

Analysis of co-citation frequencies

The mean co-citation frequencies and mean co-citation correlation coefficients of journals are calculated for comparison (shown in Table 4). Journals which have higher mean co-citation frequencies are LIS (2175.74), JLSC (2057.17), LT (1942.43), LD (1940.22) and JAL (1625.96) and their mean co-citation correlation coefficients are also relatively higher. Combining with the current reputation and influence of journals, it can be said that JLSC is ranked first among LIS journals in China. And the lower are IR (384.09), JNLC (366.70),

Table 3 The correlation matrix of journal co-citation (portion)

24	IR	384.09	0.62

JALIS (363.65) and LW (255.87). The mean co-citation frequencies and mean co-citation correlation coefficients of all journals is respectively 1101.26 and 0.76, indicating a better association among journals across the set.

Cluster analysis

LIS journals in China are divided into four clusters in this study, named cluster1, cluster2, cluster3 and cluster4. The dendrogram of the cluster analysis is shown in Fig. 1. The four-cluster solution is best fit for interpretation and the current actual situation of LIS journals in China.

There are more journals in cluster1, less in cluster2 and cluster4, least in cluster3, illustrating that the study subjects of LIS in China are focused on cluster1, cluster2 and cluster4; and cluster3 is marginal. In terms of the articles published in journals, cluster1

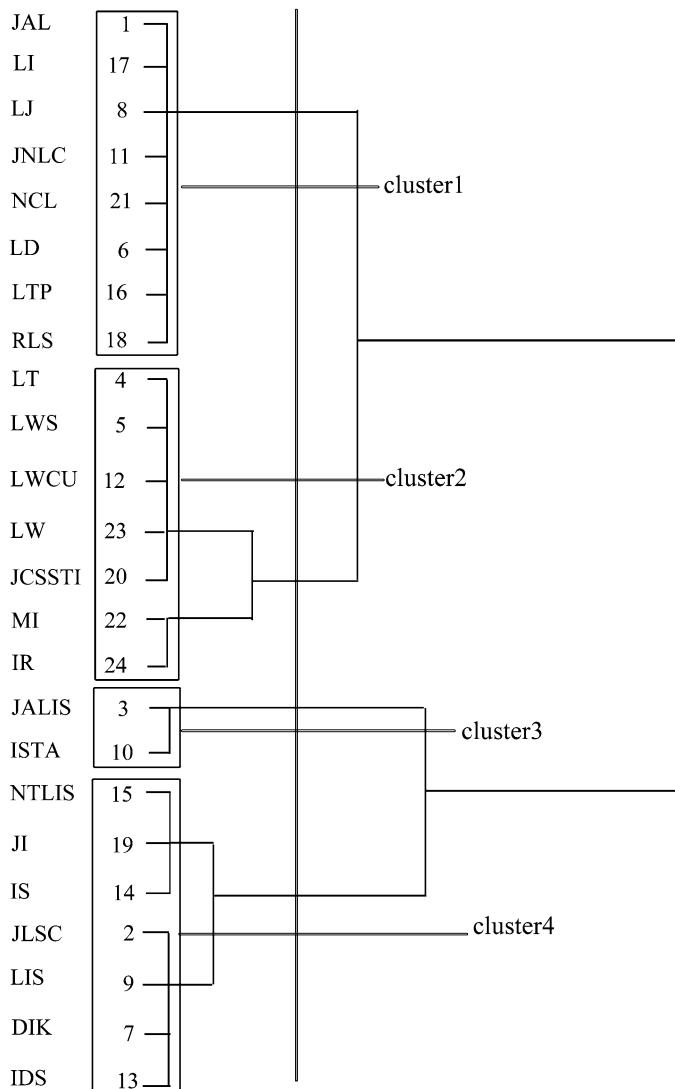

Fig. 1 Dendrogram of cluster analysis of 24 LIS journals in China

Table 5 The mean co-citation frequencies and mean co-citation correlation coefficients of the four clusters

Cluster	Mean co-citation frequencies	Mean co-citation correlation coefficients
1	1012.594	0.96
2	709.4694	0.88
3	542	0.94
4	1664.286	0.89

and cluster2 more focus on Library Science; cluster3 and cluster4 more focus on Information Science. Cluster1 and cluster2 include a total of fifteen journals (62.5% of all journals) and Library Science remains the main study area in Chinese LIS.

1. Cluster1: There are most journals with high mean co-citation frequencies and mean co-citation correlation coefficients in cluster1. Journals in cluster1 are clustered together at the first instance with the close relationship among them. However, several exceptional journals (such as NCL and JNLC) have lower co-citation frequencies and correlation coefficients in cluster1 because of the similar themes.
2. Cluster2: There are obviously two branches in cluster2: MI and IR named sub-cluster 2-a, the others named sub-cluster2-b. Journals in sub-cluster2-a focus on Information Science and sub-cluster 2-b more focus on application and practice, so it is can be said that there are no clear boundaries between Library Science and Information Science.
3. Cluster3: Cluster3 contains only two journals (JCSSTI and ISTA). The two journals are on the edge of LIS with more research topics of computers and information technology.
4. Cluster4: Seven journals have the relatively higher co-citation frequencies. Clearly cluster4 consists of two sub-clusters: one named sub-cluster 4-a including IS, NTLIS and JI (mainly related to the applications of computer technology in LIS); the other named sub-cluster 4-b including JLSC, DIK, LIS and IDS (related to research of theory and practice in LIS). The study subjects in cluster4 are inclined to research for applications in LIS as a whole.

The mean co-citation frequencies and mean co-citation correlation coefficients of the four clusters are shown in Table 5. As can be seen, cluster1 and cluster4 have the highest mean co-citation frequencies and mean co-citation correlation coefficients and journals in the two clusters have closer relationship. Especially cluster1 has the largest mean co-citation correlation coefficients, indicating the closest relationship among journals and the most centralized study subjects. Journals in cluster1 have a high status in Chinese LIS.

Multidimensional scaling analysis

In order to visualize the subject relatedness among the journals in a multivariate space, two-dimensional map is generated by MDS. The correlation degree of journals can be intuitively discerned through the location and distance in the map. Journals with high correlation coefficient are located together. The closer their locations are, the more similar their study subjects are. In this analysis, Stress is equal to 0.02703 and RSQ is equal to 0.99744; the effect of analysis is very good. Figure 2 shows the two-dimensional solution.

1. The four clusters obtained by cluster analysis were embedded into the two-dimensional map to facilitate the interpretation. Cluster1 is in the first quadrant; cluster2 is in the forth; cluster3 is in the third and cluster4 is in the second. Cluster1 is

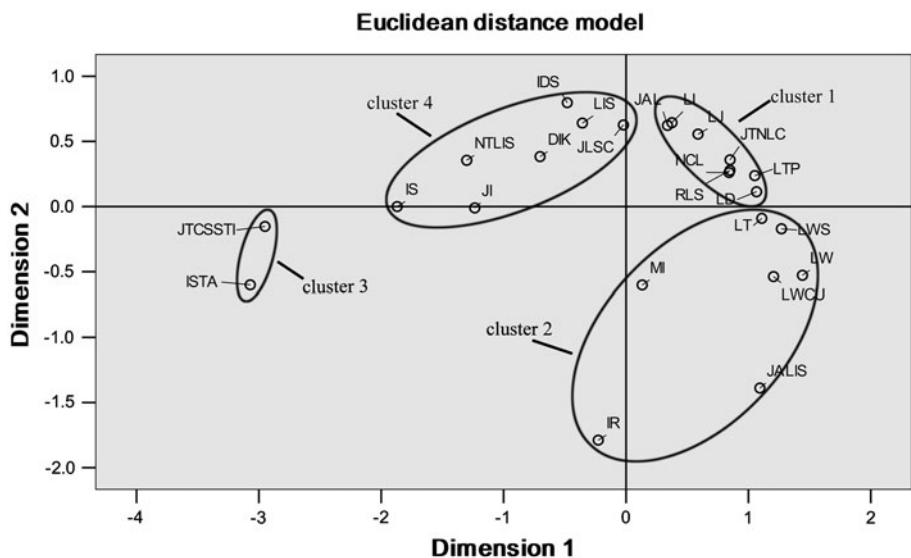

Fig. 2 Two-dimensional map of journal co-citation of LIS in China

located close to cluster2 and cluster4, in which journals have close relationship among them. The two sub clusters of cluster2 are separated far away from each other; sub-cluster2-b is closer to cluster1. Cluster3 is located in the far left of the map, in other words in the marginal location. Journals in cluster4 are relatively dispersed; sub-cluster4-b is closer to cluster1 because of its focusing subjects.

2. Combined with the cluster analysis, journals in cluster3 and cluster4 located on the left of coordinate axis focus on Information Science; journals in cluster1 and cluster2 on the right focus on Library Science. Viewed from left to right, the subject is from Information Science to Library Science. The mean co-citation frequencies and mean co-citation correlation coefficients of journals above the coordinate axis are larger than the below. Cluster1 and cluster4 are above the horizontal axis simultaneously and the number of journals in the two clusters is roughly equal, indicating that Library Science and Information Science are developing evenly in the main.
3. There are several special journals which almost overlap on the map (LI and JAL; TNLC, LJ and NCL) because of the closer relationship among them.

JLSC on the vertical axis is the bridge connecting cluster1 with cluster2 and its mean co-citation frequencies and mean co-citation correlation coefficients are relatively higher. We can initially conclude that JLSC is the core of all journals.

Factor analysis

A three-factor solution is generated in the factor analysis. As shown in Table 6, it suggests the extraction of three factors explaining 98.67% of the total variance. Although there is no perfect match between the factor assignment and the cluster assignment, there are ample similarities between the two. It should be noted that the high factor loading indicates the high status and large contribution of journal. Table 7 shows the result of the rotated factor

Table 6 The total variance explained by factor analysis

Factor	% of Variance	Cumulative (%)
1	46.96	46.96
2	36	82.959
3	15.72	98.679

analysis of the correlation coefficient matrix and the factor loadings are greater than or equal to 0.5.

1. In terms of the number of journals, three factors are significantly reduced as a trapezoid structure. The total variance of factor1 and factor2 is 82.96% and journals in these two factors are the master journals of LIS in China. Journals in factor3 whose variance is the least contribute fewer to LIS.
2. Factor1 includes all the journals in cluster1 (factor loadings are greater than 0.8), four in sub-cluster 2-b and three in sub-cluster 4-b, indicating that there are large correlation degree among them. Factor 2 contains all the journals in cluster3 and a majority in cluster4, indicating the stronger subject overlapping between cluster3 and cluster4.

3. Factor loadings of journals in cluster1 and cluster4 are relatively higher, illustrating the high status in LIS again. It is notable that there are three journals across two factors: LIS, IDS, LWCU because that there is intersection between two factors and the study subjects of the journals are comparatively extensive.
4. Journals in cluster2 and cluster4 are separated respectively because of the different focused study subjects.

Comparison with related studies

Compared with the previous related researches (e.g., Tian 2009; Song and Ye 2009), the major contributions of this paper are as follows:

1. The time span selected between 1999 and 2009, is longer than other studies, and the amount of data is large enough to guarantee the accuracy.
2. The integrated application of cluster analysis, multidimensional scaling analysis and factor analysis supplements and conforms with the results more scientifically.
3. The judgments about the clusters of journals and their subject areas are more accurate. And the correlation degrees among journals are fully and distinctly exhibited.

Consequently, the relationship structure of LIS journals in China in this study is more obvious to acquaint us with the development status.

Conclusion

Using the co-citation data of 24 LIS journals in China and taking CJFTD as the data source, we obtain clear and reasonable results about the relationship and structure of LIS studies in China.

1. As a whole, the journals of LIS in China are strongly related to each other. The LIS field in China has the stable mainstream journals group in which JLSC is the core.
2. Journals can be divided into four clusters with different focusing study subjects. The relationship in each cluster and between clusters is different.
3. The integrated tendency of Library Science and Information Science in China are getting more and more obvious, but the development is not balanced as a whole; Library Science occupies the dominant position.

This study can provide a general grasp of the structure of journals of LIS in China. This paper identifies the relationship and structure of LIS in China though the journals, but not described the network characters of journal co-citation, such as: centrality, density and core/periphery structure. Therefore, we will furthermore utilize the theory and methods of social network to analyze the data of journal co-citation and achieve more valuable results.

Appendix

See Tables 8 and 9.

WWW.SPRINGER.COM

Scientometrics is electronically available at www.akademiai.com and www.springer.com. As an added benefit to subscribers, you can now access the electronic version of every printed article along with exciting enhancements that include:

- Subscription
- Free trials to many publications
- Pay-per-view purchasing of individual articles
- Enhanced search capabilities such as full-text and abstract searching
- ActiveSearch (resubmits specified searches and delivers notifications when relevant articles are found)
- E-mail alerting of new issues by title or subject
- Custom links to your favourite titles
- Online First/Online Preview articles
